

What is linear search ?

- It is a search algorithm that go from the beginning (index 0) to the end of an array (index length - 1), compare each element with target value
- If the target is found, return true. If the target is not found after checking all elements, return false

What is it need ?

- Input: an array (haystack) and a target value (needle)
- Output: returns a boolean indicating whether the target was found in the array.

What is it Big(O) ?

- $O(n)$
- Worst case: target not in the array, so the algorithm must go through all every single element
