

Stack Data Structures

What is Stack ?

- Opposite data structure of [Queue](#) ☹☹
- LIFO (Last-in-first-out)
- elements are added and removed only from the head

How to make it ?

- push:
 - point the new element's 'next' pointer to the current head
 - update the head to point to the new element.
- push:
 - save the current head
 - move head downward
 - return the value
- peak
 - just access head.value \(\~\~)/

Function call ?

Function calls are conceptually similar to a stack, with each function call being 'pushed' onto the call stack and 'popped' off when the function completes. The memory used for these calls is literally called the 'stack'.
